Field of the Invention The invention relates to an imaging lens and an imaging apparatus, more particularly to an imaging lens and an imaging apparatus with a telephoto lens. 2. Description of the Related Art In recent years, with the popularity of mobile terminals having camera functionalities, the demand for miniaturizing an optical system is increasing. The sensor of ordinary photographing cameras is typically a CCD (Charge-Coupled Device) image sensor or a CMOS (Complementary Metal-Oxide Semiconductor) image sensor. As advanced semiconductor manufacturing technologies have allowed the pixel size of sensors to be reduced and compact optical systems have gradually evolved toward the field of higher megapixels, there is an increasing demand for compact optical systems featuring better image quality. A conventional optical system employed in a conventional photographing camera, e.g., a 6-megapixel camera, typically utilizes five or six lens elements. In the field of mobile terminals, the demand for compact optical systems featuring better image quality has encouraged the adoption of the design of four lens elements. An optical system composed of four lens elements, however, cannot simultaneously achieve good imaging quality and a compact size at the same time. Moreover, regarding the conventional optical system employed in a conventional photographing camera, the lens elements have positive, negative and positive refractive powers. Regarding the optical system employed in a conventional mobile terminal, the lens elements have positive, negative and positive refractive powers. However, positive, negative and positive powers are contradictory to each other. That is to say, a positive power usually requires a negative power, and a negative power usually requires a positive power. Therefore, it is difficult to achieve a good optical performance with respect to both the optical system employed in a conventional photographing camera and the optical system employed in a conventional mobile terminal.
