SVN is a version control system that is most widely used for version control, that is the management of software source code. This is used in projects where the source code is managed by more than one person and source files may need to be shared or distributed to other developers. The description of SVN Various types of version control software are used in projects. The most popular among them are centralized revision control systems.

One such system is Subversion, which is open source and designed for version control. In this system, a repository is created to store the project source files in a repository server. There is a local server and a working copy in the local machine. The files are stored in the repository, and the version control system helps the users see the differences between revisions, and also the changes made to the files. All the changes made by the users are kept in a record called a commit. The repository server holds all the

revisions of the project source code. The repository server is a server where the source code is stored and managed. The working copy is the local repository where the users can work on the project. The working copy may or may not be the same as the repository. Working copy is the local repository where the users can work on the project. The repository and the working copy are connected to each other, so the changes made in the working copy are uploaded to the repository, and the repository reflects the changes in the working

copy. This process is called Committing. The following are some of the main features of SVN:

- Source code version control Repository
- Working copy
- Commits
- SVN repositories are identified with the prefix `svn://`
- Repositories are also referred to as repositories.
- Source code repositories are used to manage the source code in a project.
- A repository contains the project source code files and directories.
- Source code in the repository is managed as a project.
- The working copy of the source code is a copy of

the repository, which is the version of the source code that can be worked on locally by the users.

Creating a repository

To create a repository, one needs to specify a server. An SVN server is one which manages the repository. Repositories are server software that are used to create, manage and store the source code of a project. SVN also provides a client (a software that can work with a repository) and a daemon (a server process), which is used to interact with the SVN server and to handle version control operations.
